1.2 Download ClinVar VCF

`ftp://ftp.ncbi.nlm.nih.gov/pub/clinvar/vcf_GRCh37/clinvar.vcf.gz`

ClinVar is the central repository for variant interpretations. Relevant information from the VCF includes:

(a) CLNSIG = “Variant Clinical Significance, 0 - Uncertain, 1 - Not provided, 2 - Benign, 3 - Likely benign, 4 - Likely pathogenic, 5 - Pathogenic, 6 - Drug response, 7 - Histocompatibility, 255 - Other”

(b) CLNDBN = “Variant disease name”

(c) CLNDSDBID = “Variant disease database ID”

(d) INTERP = Pathogenicity (likely pathogenic or pathogenic; CLNSIG = 4 or 5)

Processed ClinVar data frame 126349 x 14 (selected rows/columns):

VAR_ID	CHROM	POS	ID	REF	ALT	CLNSIG	CLNDBN
1_955597_G_T	1	955597	rs115173026	G	T	2	not_specified

File saved as `download_output.txt` in `Supplementary_Files`

1.4 Collect 1000 Genomes Phase 3 Populations Map

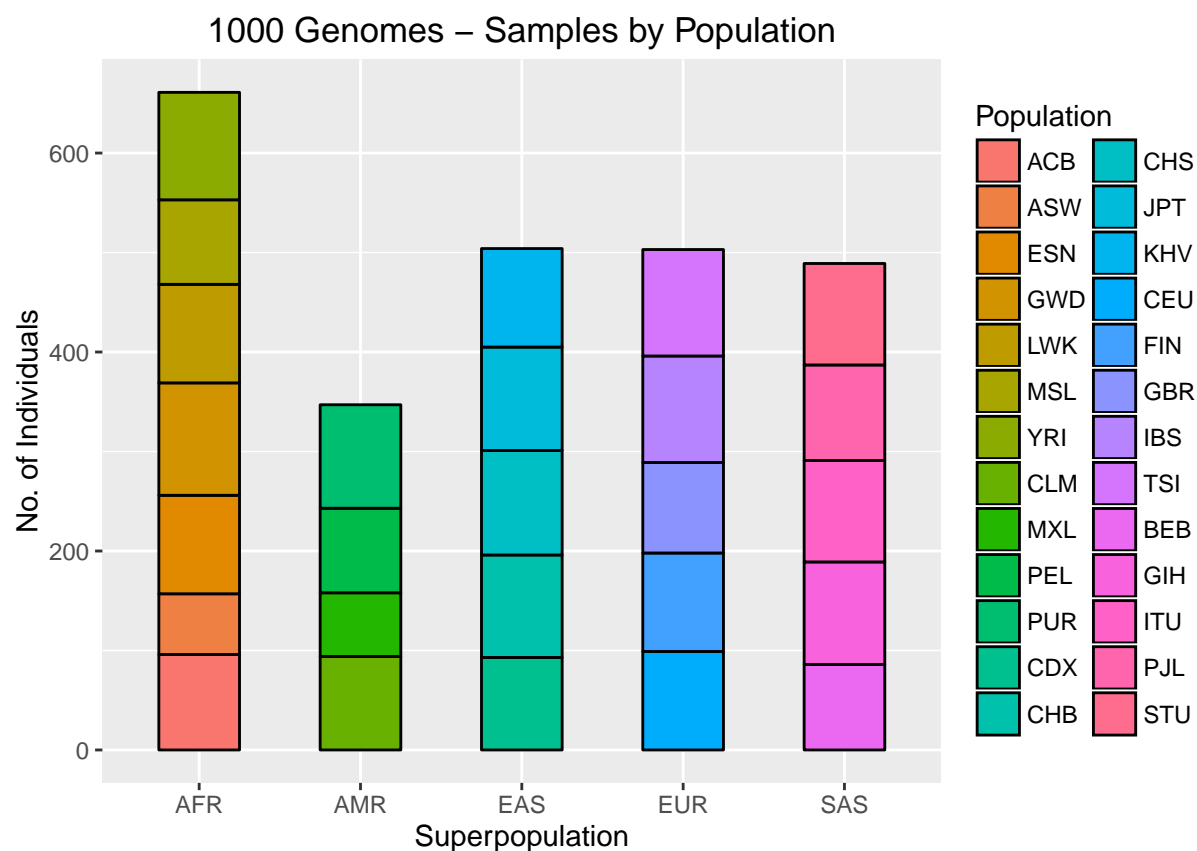

This will allow us to assign genotypes from the 1000 Genomes VCF to ancestral groups.

From: ftp://ftp.1000genomes.ebi.ac.uk/vol1/ftp/release/20130502/integrated_call_samples_v3.20130502.ALL.panel

Phase 3 Populations Map Table: 2504 x 4 (selected rows)

Population Distribution

1.5 Import and Process 1000 Genomes VCFs

- Unnest the data frames to 1 row per variant_ID key (CHROM_POSITION_REF_ALT).
- Remove all insertions, deletions, CNV, etc, and keep only missense variants (1 REF, 1 ALT)
- For 1000 Genomes: convert genomes to allele counts. For example: (0|1) becomes 1, (1|1) becomes 2. Multiple alleles are unnested into multiple counts. For example: (0|2) becomes 0 for the first allele (no 1s) and 1 for the second allele (one 2).

Processed 1000 Genomes VCFs: 139335 x 2516 (selected rows/columns):

GENE	AF_1000G	VAR_ID	CHROM	POS	ID	REF	ALT
APC	0.0001997	5_112043211_A_G	5	1.12e+08	rs554351451	A	G

1.6 Import and Process ExAC VCFs

- Unnest the data frames to 1 row per variant_ID key (CHROM_POSITION_REF_ALT).
- Remove all insertions, deletions, CNV, etc, and keep only missense variants (1 REF, 1 ALT)
- Collect superpopulation-level allele frequencies: African = AFR, Latino = AMR, European (Finnish + Non-Finnish) = EUR, East.Asian = EAS, South.Asian = SAS.

Processed ExAC VCFs: 58873 x 45 (selected rows/columns):

GENE	AF_EXAC	AF_EXAC_AFR	AF_EXAC_AMR	AF_EXAC_EAS	AF_EXAC_EUR
APC	8.13e-05	0	0	0	0

1.8 Comparison with ClinVar Browser Query Results

clinvar_query.txt contains all results matched by the search query: “(APC[GENE] OR MYH11[GENE]... OR WT1[GENE]) AND (clinsig_pathogenic[prop] OR clinsig_likely_pathogenic[prop])” from the ClinVar website. The exact query is saved in /Supplementary_Files/query_input.txt
This presents another way of collecting data from ClinVar.

Intermediate step: convert hg38 locations to hg19 using the Batch Coordinate Conversion tool (liftOver) from UCSC Genome Browser Utilities.

ClinVar Query Results Table (substitutions only): 6714 x 13 (selected rows/columns)

VAR_ID	Gene(s)	Condition(s)	Frequency
X_100652891_C_G	GLA	Fabry disease	GMAF:0.00050(G)
11_47374186_C_G	MYBPC3	Primary familial hypertrophic cardiomyopathy	GMAF:0.00020(G)

1_17380507_G_C	SDHB	Cowden syndrome 2	GO-ESP:0.01323(C)

Breakdown of ClinVar Query Results Table:

Subset	Number_of_Variants
Initial Count	12525
Filter Substitutions (N>N')	6732
Filter Coupling/Bad-Locations	6714
In ClinVar VCF	509
In LP/P-ClinVar VCF	503
^ & ACMG & ExAC	49
^ & ACMG & 1000 Genomes	9
^ & ACMG & ExAC & 1000 Genomes	8

Note the 12-fold reduction after merging the online query results with the VCF.

2 Plot Summary Statistics Across Populations

2.1 Distribution of Allele Frequencies

The distribution of allele frequencies is approximately Poisson, with “Poissonness plot” correlation = 0.99. The Poissonness plot (Hoaglin 1980) is defined as the plot of $\log(x_k) + \log(k!)$ vs. k , as shown below:

2.2 Overall Non-Reference Sites

2.2.0.1 For 1000 Genomes

Each individual has n non-reference sites, which can be found by counting. The mean number is computed for each population.

Ex: the genotype of 3 variants in 3 people looks like this:

	HG00097	HG00099	HG00100
Variant 1	0	2	1
Variant 2	0	0	1
Variant 3	0	0	1

Count the number of non-reference sites per individual:

HG00097	HG00099	HG00100
0	1	3

Mean = 1.33

Note: the error bars denote standard deviation, not standard error.

2.2.0.2 For ExAC

The mean number of non-reference sites is $E(V)$, where $V = \sum_{i=1}^n v_i$ is the number of non-reference sites at all variant positions v_1 through v_n .

At each variant site, the probability of having at least 1 non-reference allele is $P(v_i) = P(v_{i,a} \cup v_{i,b})$, where a and b indicate the 1st and 2nd allele at each site.

If the two alleles are independent, $P(v_{i,a} \cup v_{i,b}) = 1 - (1 - P(v_{i,a}))(1 - P(v_{i,b})) = 1 - (1 - AF(v_i))^2$

If all variants are independent, $E(V) = \sum_{i=1}^n 1 - (1 - AF(v_i))^2$ for any set of allele frequencies.

Ex: the allele frequencies of 3 variants across the 5 superpopulations looks like this:

	AFR	AMR	EAS	EUR	SAS
Variant 1	0.1	0.2	0	0	0.3
Variant 2	0.2	0	0.3	0	0.1

The probability of having at least 1 non-reference site at each variant - (0|1) (1|0) or (1|1) is given by $1 - (1 - AF)^2$. Note that this is approximately $2 * AF$ when AF is small:

	AFR	AMR	EAS	EUR	SAS
Variant 1	0.19	0.36	0	0	0.51
Variant 2	0.36	0	0.51	0	0.19

By linearity of expectation, the expected (mean) number of non-reference sites is $\sum E(V_i) = \sum (columns)$.

AFR	AMR	EAS	EUR	SAS
0.55	0.36	0.51	0	0.7

2.3 Pathogenic Non-Reference Sites

2.3.0.1 For 1000 Genomes and ExAC

This is the same procedure as above, but performed only on the subset of variants that are pathogenic.

2.4 Fraction of Individuals with Pathogenic Sites

2.4.0.1 For 1000 Genomes

We can count up the fraction of individuals with 1+ non-reference site(s) in each population. This is the fraction of individuals who would receive a positive genetic test result in at least 1 of the ACMG-56 genes.

Ex: the genotype of 3 variants in 3 people looks like this:

	HG00097	HG00099	HG00100
Variant 1	0	2	1
Variant 2	0	0	1
Variant 3	0	0	1

Count each individual as having a non-reference site (1) or having only reference sites (0):

HG00097	HG00099	HG00100
0	1	1

Mean = 0.667

2.4.0.2 For ExAC

The probability of having at least 1 non-reference site is $P(X)$, where X indicates a non-reference site at any variant position v_1 through v_n .

Recall that $P(v_i) = P(v_{i,a} \cup v_{i,b}) = 1 - (1 - AF(v))^2$ when alleles are independent.

If all alleles are independent, $P(X) = P(\bigcup_{i=1}^n v_i) = 1 - \prod_{i=1}^n (1 - AF(v_i))^2$

Ex: the allele frequencies of 3 variants across the 5 superpopulations looks like this:

	AFR	AMR	EAS	EUR	SAS
Variant 1	0.1	0.2	0	0	0.3
Variant 2	0.2	0	0.3	0	0.1

The probability of having at least 1 non-reference site at each variant - (0|1) (1|0) or (1|1) is given by $1 - (1 - AF)^2$. Note that this is approximately $2 * AF$ when AF is small:

	AFR	AMR	EAS	EUR	SAS
Variant 1	0.19	0.36	0	0	0.51
Variant 2	0.36	0	0.51	0	0.19

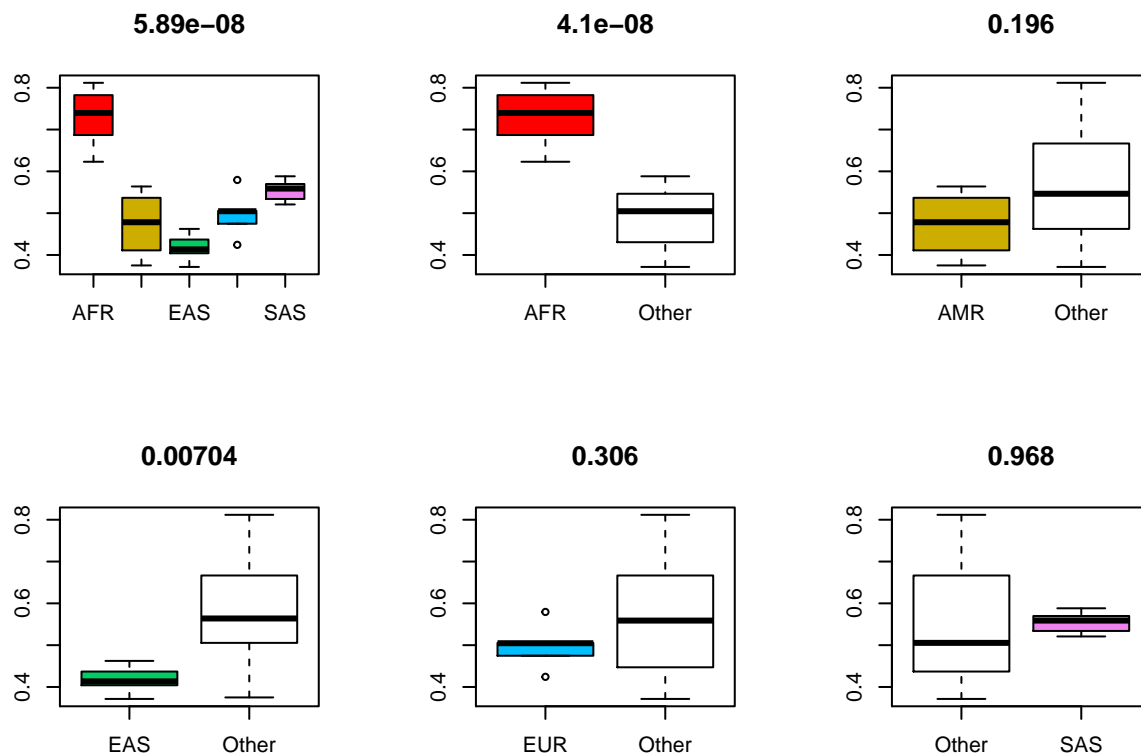

The expected (mean) number of non-reference sites is given by $1 - \prod (1 - AF)^2$.

AFR	AMR	EAS	EUR	SAS
0.4816	0.36	0.51	0	0.6031

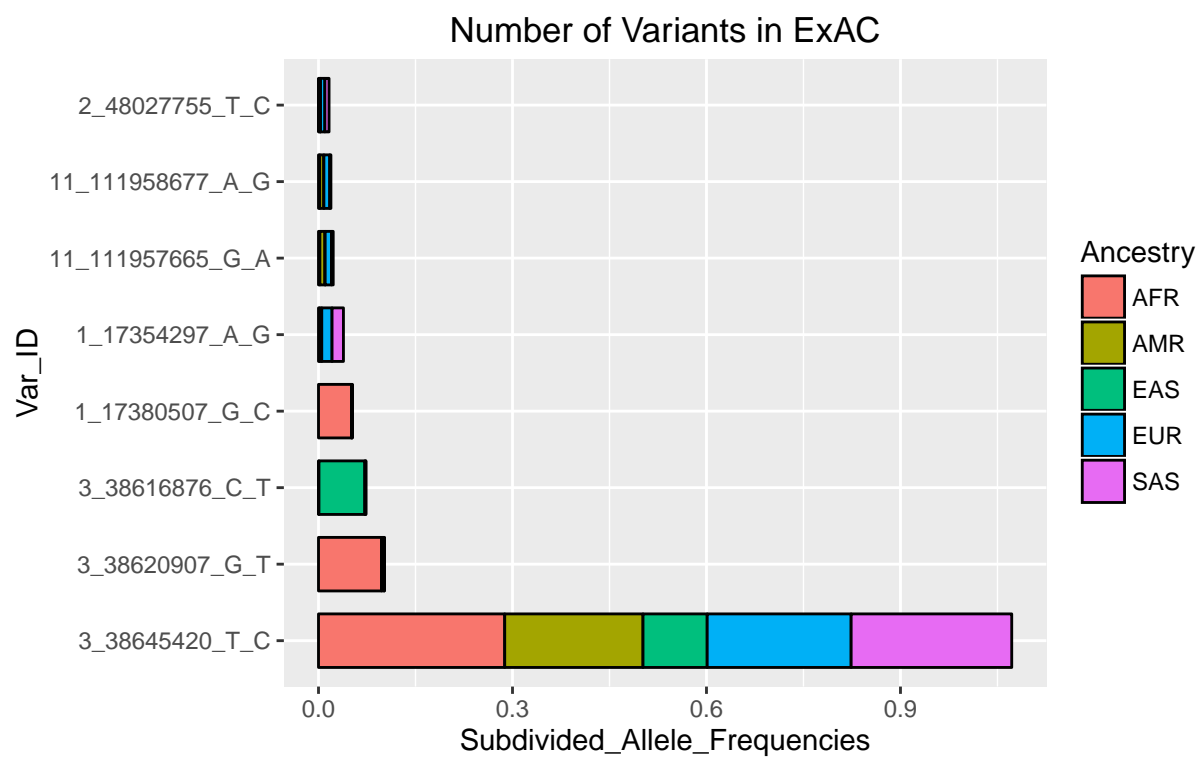

2.5 Test Statistics for Ancestral Differences

F-statistic/T-statistic: probability that the different groups are sampled from distributions with the same mean. These plots are from 4(a) - 1000 Genomes Fraction with 1+ Non-Reference Site, but can be replicated for plots 2(ab) and 3(ab) as well.

2.6 Common Pathogenic Variants by Ancestry

3 Penetrance Estimates

3.1 Bayes' Rule as a Model for Estimating Penetrance

Let V_x be the event that an individual has 1 or more variant related to disease x , and D_x be the event that the individual is later diagnosed with disease x .

In this case, we can define the following probabilities:

1. Prevalence = $P(D_x)$
2. Allele Frequency = $P(V_x)$
3. Allelic Heterogeneity = $P(V_x|D_x)$
4. Penetrance = $P(D_x|V_x)$

By Bayes' Rule, the penetrance of a variant related to disease x may be defined as:

$$P(D_x|V_x) = \frac{P(D_x) * P(V_x|D_x)}{P(V_x)} = \frac{\text{Prevalence} * \text{Allelic.Heteogeneity}}{\text{Allele.Frequency}}$$

To compute penetrance estimates for each of the diseases related to the ACMG-56 genes, we will use the prevalence data we collected into `Literature_Prevalence_Estimates.csv`, allele frequency data from 1000 Genomes and ExAC, and a broad range of values for allelic heterogeneity.

3.2 Import Literature-Based Disease Prevalence Data

Data Collection: 1. Similar disease subtypes were grouped together (e.g., the 8 different types of familial hypertrophic cardiomyopathy), resulting in 30 disease categories across 56 genes.
 2. The search query "[disease name] prevalence" was used to find articles using Google Scholar.
 3. Prevalence estimates were recorded along with URL, journal, region, publication year, sample size, first author, population subset (if applicable), date accessed, and potential issues. Preference was given to studies with PubMed IDs, more citations, and larger sample sizes.

Prevalence was recorded as reported: either a point estimate or a range. Values of varying quality were collected across all diseases.

Table of Literature-Based Estimates of Disease Prevalence 30 x 16 (selected rows/columns):

Gene	Disease	Disease_MIM	Tags
BRCA1;BRCA2	Breast-ovarian cancer familial	604370;612555	breast;ovarian
SCN5A	Brugada syndrome	601144	brugada
COL3A1	Ehlers-Danlos syndrome	130050	ehler;danlos
TP53	Li-Fraumeni syndrome	151623	fraumeni

Table continues below

Inverse.Prevalence.1	Inverse.Prevalence.2	year	first.author	citations
104	NA	2013	NA	NA
10000	2000	2006	Antzelevitch	11
20000	NA	2010	Malfait	116
20000	5000	1999	Schneider	47

3.3 Distribution of Prevalences

3.4 Collect and Aggregate Allele Frequencies at the Disease-Level

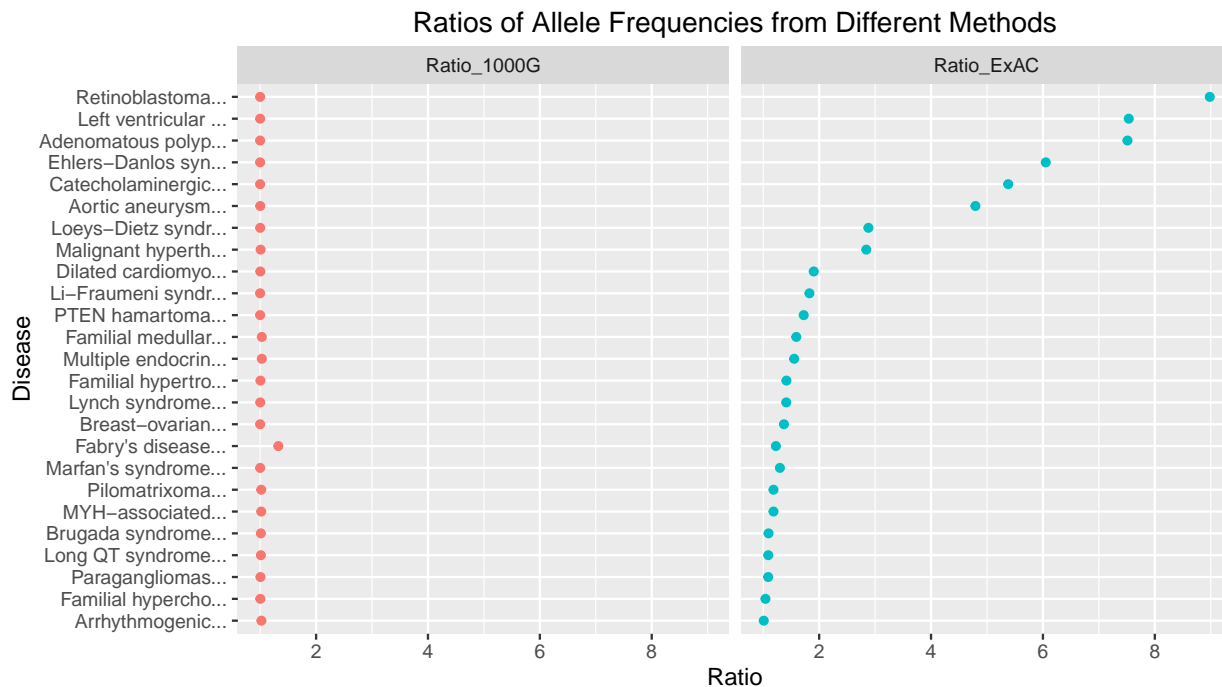

We define $AF(disease)$ as the probability of having at least 1 variant associated with the disease.

The frequencies across the relevant variants can be aggregated in two ways:

- (1) By direct counting, from genotype data in 1000 Genomes.
- (2) $AF(disease) = 1 - \prod_{variant} (1 - AF_{variant})$, from population data in ExAC (assumes independence).

Ratio_1000G (red,left) computes $AF(\text{calculation in 1000 Genomes}) / AF(\text{counting in 1000 Genomes})$.
Ratio_ExAC (blue,right) computes $AF(\text{calculation in ExAC}) / AF(\text{counting in 1000 Genomes})$.

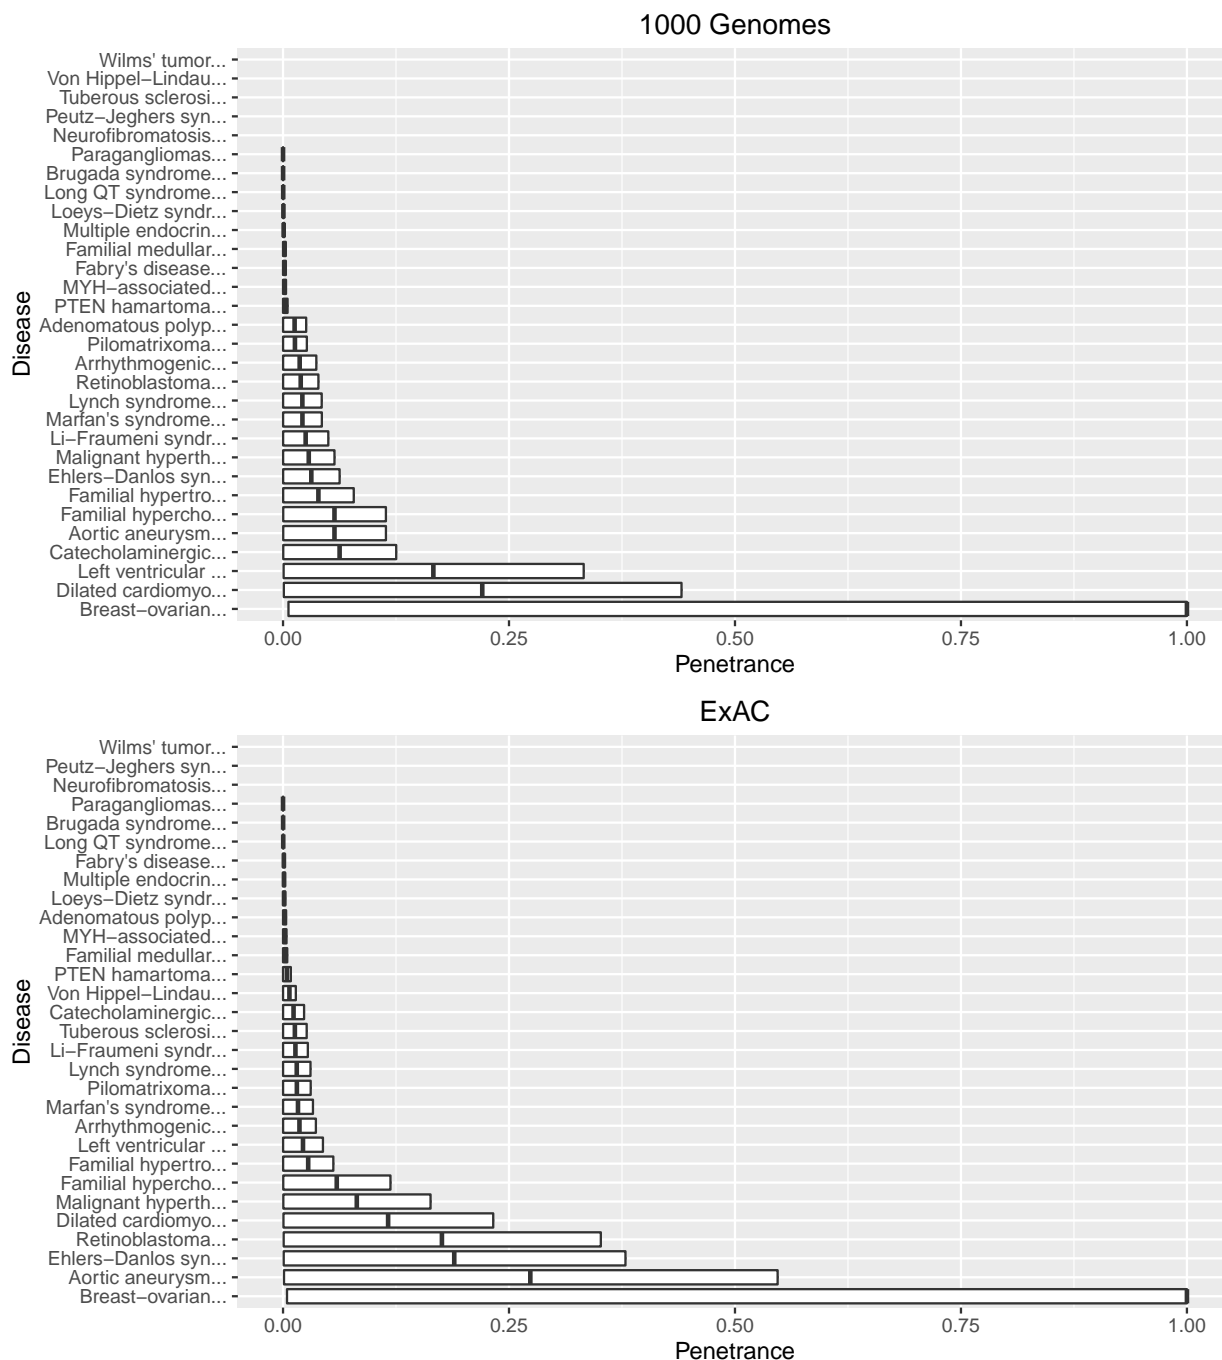

Sampling 1000 variants from 1000 Genomes variants to test deviations from assuming independence.
Repeat 10 times and plot the disease_allele frequencies (10 of each).

Pearson correlation: 0.99
Mean ratio (CALC/COUNT): 1.07

3.5 Penetrance as a Function of $P(V|D)$

The left end of the boxplot indicates $P(V|D) = 0.001$,
the bold line in the middle indicates $P(V|D) = 0.25$,
the right end of the boxplot indicates $P(V|D) = 0.5$.

Note 1: the empty lines at the top all indicate no allele frequency (disease_AF) data.

Note 2: For breast-ovarian cancer, mean theoretical penetrance > 1 . This is because the assumed allelic heterogeneity (0.25) is greater than is possible, given the empirical prevalence and allele frequencies.

3.6 Penetrance as a Function of $P(D)$

Disease	Prevalence_Ratio
Retinoblastoma	1.3
Marfan's syndrome	1.5
Lynch syndrome	3.0
Adenomatous polyposis coli	3.3
Li-Fraumeni syndrome	4.0
Parangliomas	4.0
Pilomatrixoma	4.0
Brugada syndrome	5.0
Peutz-Jeghers syndrome	12.0
Left ventricular noncompaction	18.6

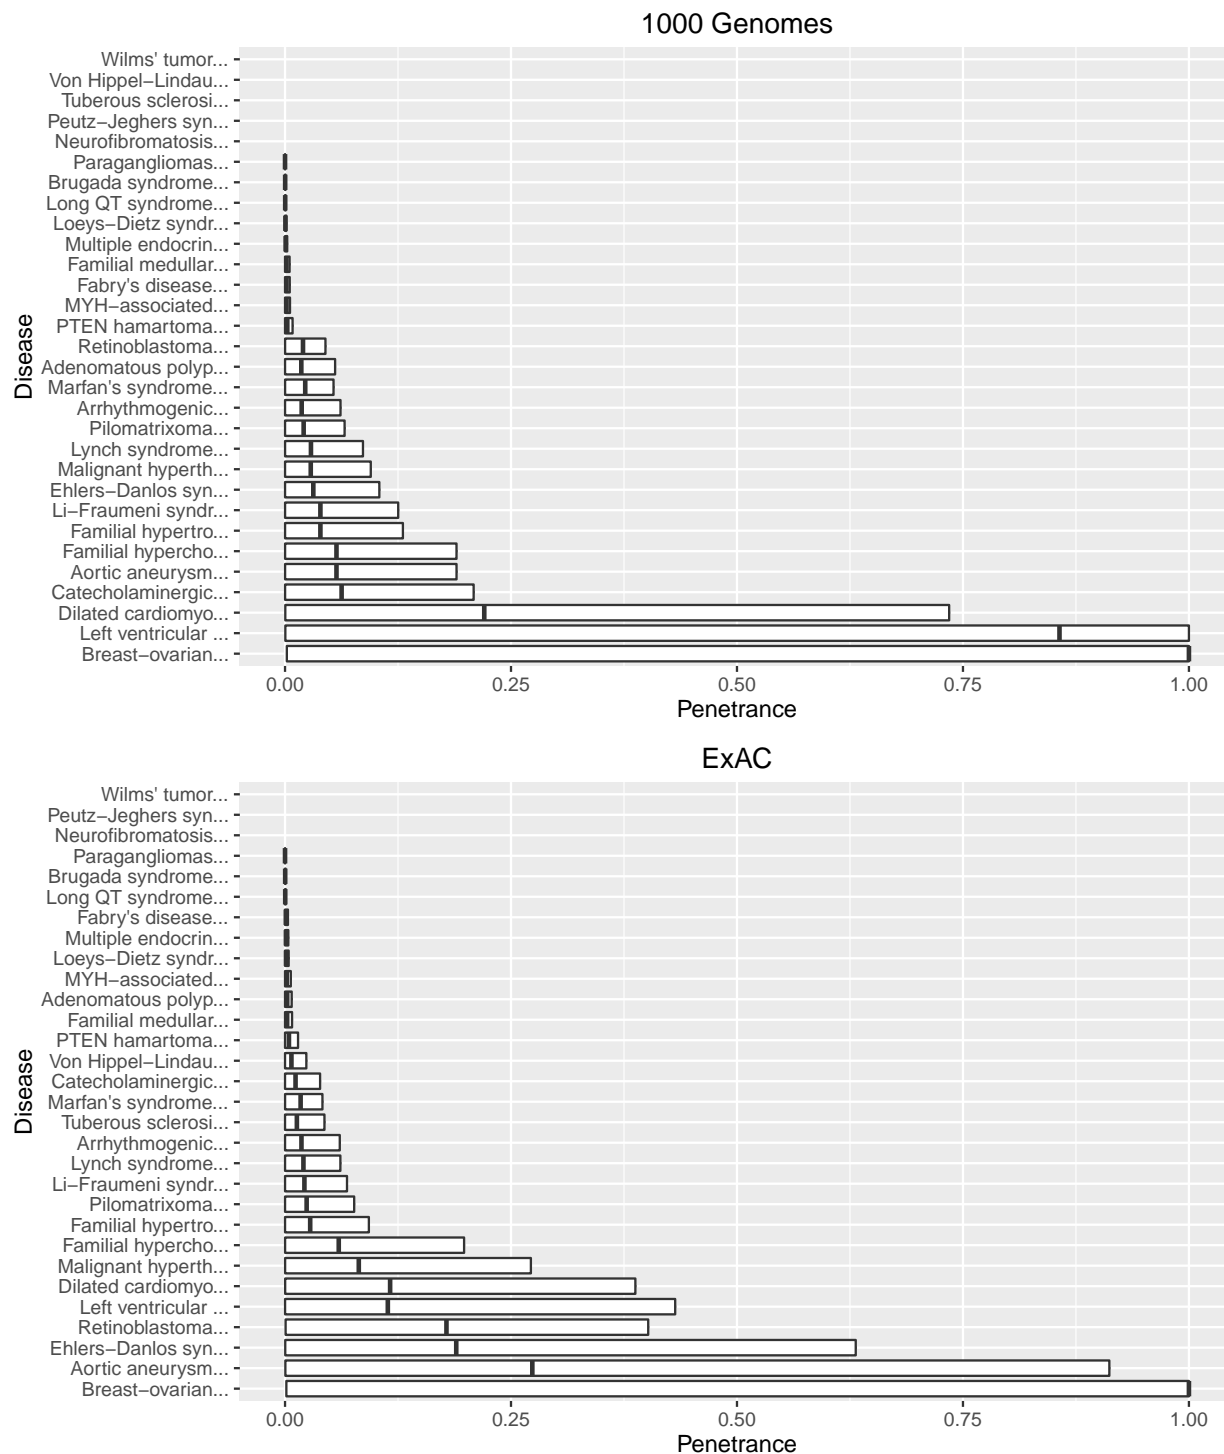

The left end of the boxplot indicates $P(D)$ = upper value,
the bold line in the middle indicates $P(D)$ = mean(values),
the right end of the boxplot indicates $P(D)$ = lower value.

This can only be computed in 10 cases where a prevalence range was given, rather than a point estimate.

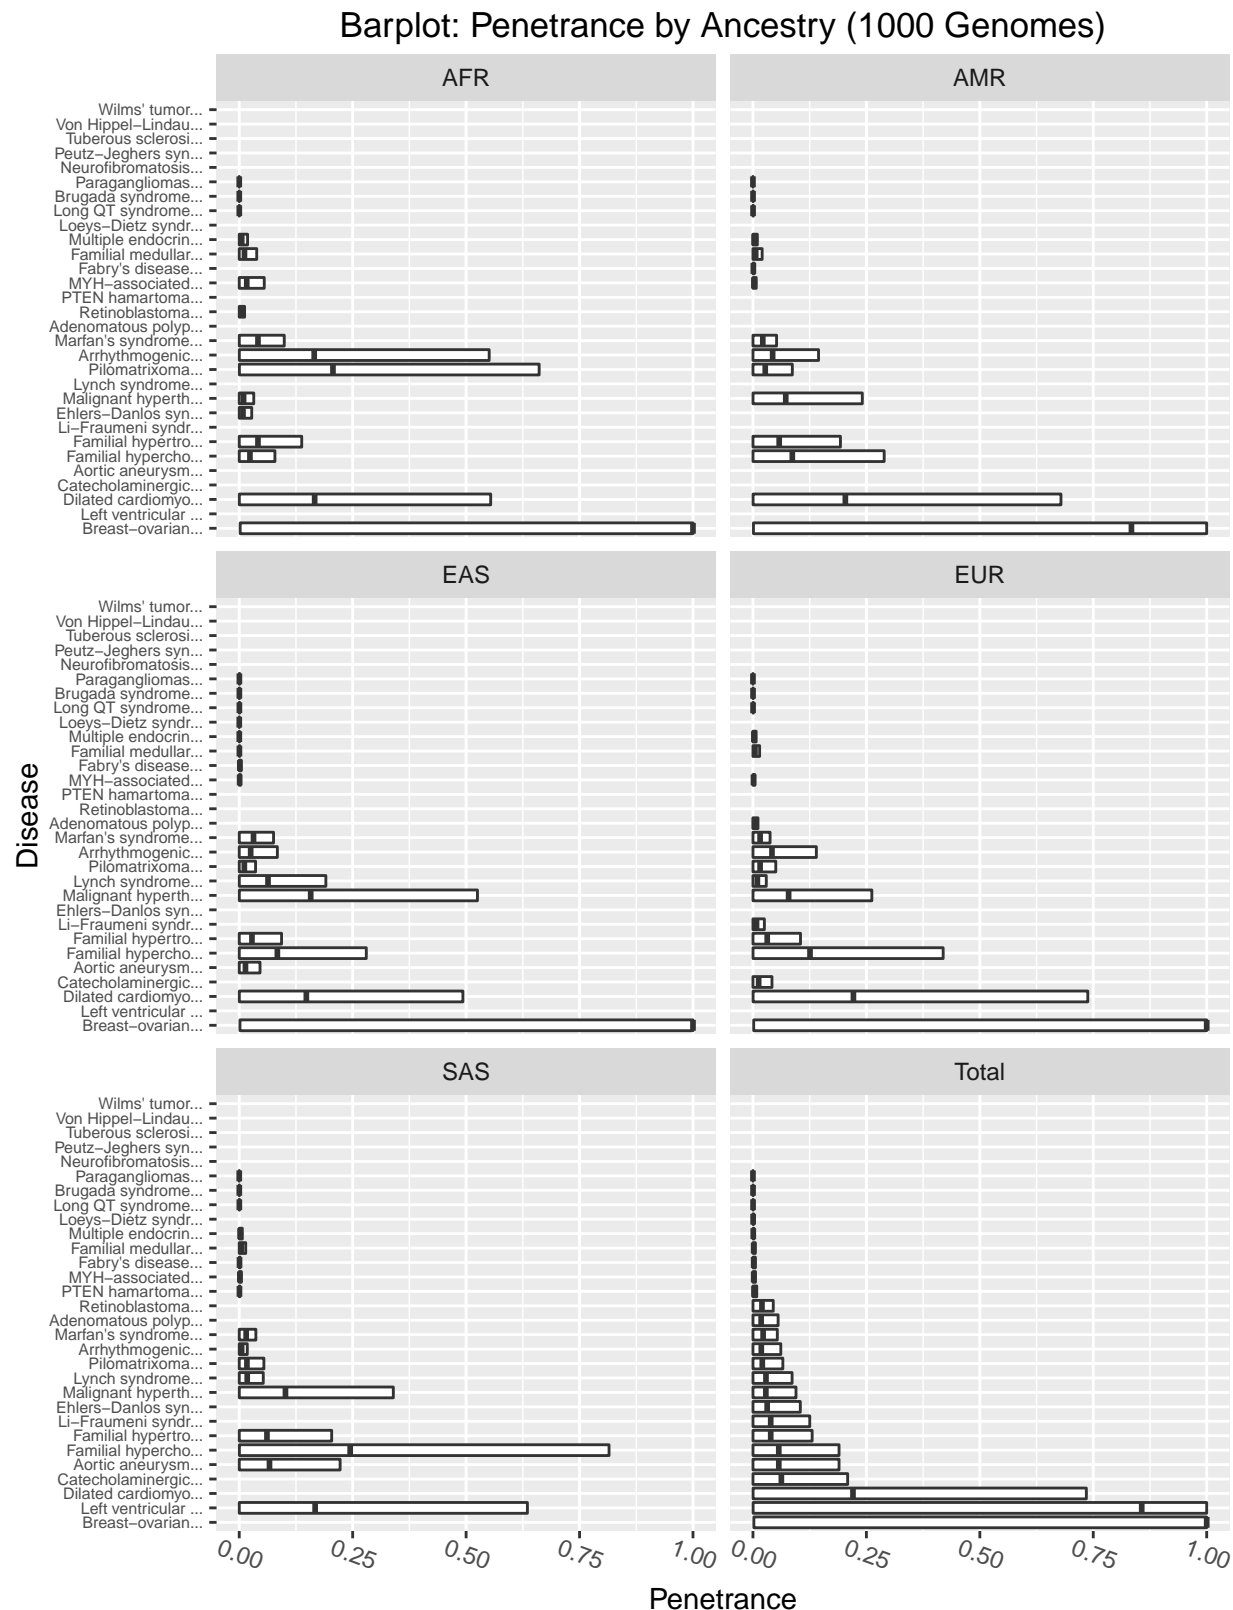

3.7 Max/Min Penetrance as a Function of $P(D)$ and $P(V|D)$

The left end of the boxplot indicates $P(D)$ AND $P(V|D)$ = lower value,
the bold line in the middle indicates $P(D)$ AND $P(V|D)$ = mean(values),
the right end of the boxplot indicates $P(D)$ AND $P(V|D)$ = upper value.

Note: Prevalence ranges of 5x were assumed for all point estimates of prevalence.
For example: a point estimate of 0.3 would be given the range [0.1, 0.5].

3.9 Empirical CDFs for All Penetrance Plots

3.10 Comparing Mean Penetrance between ExAC and 1000 Genomes

The Pearson correlation is 0.76.

Max penetrance values computed using 1000 Genomes are 0.944-fold larger than those computed using ExAC.
